Q: Is it safe to continue biologic agents during surgery in patients with inflammatory bowel disease?

A: Patients with inflammatory bowel disease who are taking monoclonal antibodies against tumor necrosis factor alpha (TNF), interleukins 12 and 23, or integrin can continue taking them around the time of surgery, but small-molecule drugs such as tofacitinib should be withheld.

Inflammatory bowel disease encompasses Crohn disease and ulcerative colitis, and biologic drugs now play an integral role in the treatment of both. Biologic therapy is supplanting thiopurines as the main treatment for inflammatory bowel disease, leading to debate regarding how these drugs should be managed preoperatively in patients undergoing surgery, due to concern for increased risk of postoperative complications.

■ BIOLOGIC AGENTS

Anti-TNF drugs

The most studied of the biologics with respect to perioperative management have been the anti-TNF drugs, namely:

- **Infliximab and biosimilars** such as infliximabs axxq, dyyb, abda, and qbtx
- **Adalimumab and biosimilars** such as adalimumabs bwwd, afzb, adza, adbm, bwwd, and atto
- **Certolizumab**.

Studies of anti-TNF drugs

While several meta-analyses have attempted to clarify the effect of these drugs on postoperative outcomes, the results have been conflicting.

Billioud et al,1 in a meta-analysis, concluded that preoperative anti-TNF use slightly increases overall postoperative complications in patients with inflammatory bowel disease, and particularly infectious complications in patients with Crohn disease.

Ali et al,2 in another meta-analysis, also found a higher risk of complications in patients with Crohn disease receiving preoperative anti-TNF agents (and corticosteroids).

Narula et al3 and Yang et al4 performed meta-analyses demonstrating similar results, both reporting higher rates of total, infectious, and noninfectious postoperative complications in patients with Crohn disease who received infliximab within 30 days before surgery.

Although these studies suggest that anti-TNF therapy should be discontinued before surgery, other studies did not detect a higher risk of infectious complications with anti-TNF therapy.

Xu et al,5 in a 2019 meta-analysis, found no significant difference in the rates of overall, major, minor, infectious, noninfectious, surgical, and medical complications between 1,407 patients with Crohn disease treated preoperatively with infliximab and 4,589 patients who were not.

Yang et al6 analyzed 13 studies with a total of 2,933 patients with ulcerative colitis receiving infliximab. They similarly found no correlation between infliximab therapy and postoperative morbidity.

Rosenfeld et al7 reported results similar to those of Yang et al, but in patients with Crohn disease.

Most of the studies included in these meta-analyses were retrospective, were performed at single centers, and had significant heteroge-
SAFETY OF BIOLOGIC AGENTS

neity and small sample sizes. They also varied significantly in confounding variables that were not controlled for such as concomitant medical therapy. Steroid use, in particular, is known to increase the risk of infectious complications in patients with ulcerative colitis or Crohn disease in the perioperative period.8,9

The Postoperative Infection in Inflammatory Bowel Disease (PUCCINI) trial10 was perhaps the best study to date to examine postoperative infectious complications in patients with Crohn disease or ulcerative colitis who had been treated preoperatively with anti-TNF drugs. It prospectively enrolled 955 patients undergoing abdominal surgery, of whom 382 had been treated with anti-TNFs preoperatively and 573 had not. Serum anti-TNF levels were measured preoperatively and reported as either detectable or undetectable. The investigators found no significant increases in any infection (19.4% vs 20.2%, P = .80) or surgical site infections (12.3% vs 12.7%, P = .92) in the anti-TNF recipients compared with nonrecipients. Further, detectable serum anti-TNF levels were not associated with higher rates of any infection.10

As the first large prospective study of its kind, the PUCCINI trial is currently the best source of information on the preoperative management of anti-TNF therapy in inflammatory bowel disease patients undergoing abdominal surgery.

Ustekinumab
Ustekinumab, a monoclonal antibody targeting interleukins 12 and 23, was approved in 2016 for use in Crohn disease, though it was previously used off-label for patients for whom anti-TNF therapy failed. After induction, ustekinumab maintenance therapy is given every 8 weeks.

In a multicenter Canadian study11 comparing preoperative anti-TNF use and preoperative ustekinumab use in patients with Crohn disease undergoing abdominal surgery, there were no significant differences in postoperative complications, length of hospital stay, or mortality rates.

These results were mirrored in a US study of 44 ustekinumab-treated patients and 169 anti-TNF-treated patients undergoing major abdominal surgery. There was no difference in postoperative surgical site infection rates or hospital readmission rates between the 2 cohorts.12

Anti-integrin antibodies
Vedolizumab and natalizumab are the most widely used anti-integrin antibodies. The former is a gut-specific antibody that selectively inhibits lymphocyte trafficking and inflammatory response in the gastrointestinal tract. It is given every 8 weeks after induction but can be dosed as often as every 4 weeks in patients with severe disease or those who lose response to initial treatment.13

Studies of anti-integrin antibodies
Law et al14 conducted a meta-analysis comparing 5 studies with 307 patients receiving vedolizumab, 490 patients receiving anti-TNF drugs, and 535 patients not receiving biologic agents. The analysis revealed no significant difference in rates of overall postoperative complications or infectious complications between those on vedolizumab and either those on anti-TNF agents or those with no biologic exposure.

Yung et al15 recently performed another meta-analysis of 4 studies in 1,080 patients with Crohn disease or ulcerative colitis, who had vedolizumab exposure, anti-TNF exposure, or no exposure to biologics. The ulcerative colitis patients with vedolizumab exposure did have a significantly lower overall postoperative complication rate compared with those with anti-TNF exposure. However, there were no other significant differences in infectious, surgical site, or major complications in those with either ulcerative colitis or Crohn disease between vedolizumab and anti-TNF or vedolizumab and no biologics. Likewise, there were no significant differences in the rates of additional surgery for complications.15

SMALL-MOLECULE DRUGS
Tofacitinib, a JAK inhibitor
Tofacitinib, approved in May 2018, is one of the newest medications for moderate to severe ulcerative colitis. This small molecule is a Janus kinase (JAK) inhibitor that is taken orally twice a day. It has been approved for use in rheumatoid arthritis since 2012.16
As tofacitinib is a recent addition to inflammatory bowel disease therapy, there are limited data assessing its perioperative use. Current guidelines from the American College of Rheumatology (ACR) and the American Association of Hip and Knee Surgeons (AAHKS) recommend holding tofacitinib starting 7 days before total knee or total hip surgery due to increased risk of infectious complications. It can be resumed as early as 14 days after surgery.17

Currently, tofacitinib is indicated for moderate to severe rheumatoid arthritis, ulcerative colitis, and Crohn disease. However, its use is not standardized due to the recent emergence of groundbreaking therapies. Studies have shown promising preliminary results in clinical trials and may soon be approved for treating inflammatory bowel disease. Because these drugs are so new, their influence on operative outcomes at this time is unknown.

Our recommendations differ from those included in the 2017 professional society guidelines,17 which recommend holding all biologic medications as close to 1 dosing cycle as possible before all elective procedures. The deviation of our recommendations from these guidelines is due to the recent emergence of groundbreaking studies such as the PUCCINI trial which have allayed fears of increased risks of postoperative complications with biologic use in inflammatory bowel disease patients.

### OUR RECOMMENDATIONS

#### Biologics

In summary, to date, several single-center retrospective reviews, prospective studies, and meta-analyses exploring postoperative complications in inflammatory bowel disease patients on anti-TNF therapy have demonstrated mixed results. However, nearly all of the earlier studies had notable weaknesses, including marked heterogeneity among studies in meta-analyses and lack of controlled variables. On the contrary, the landmark PUCCINI trial has emerged as the most instrumental study of preemptive anti-TNF therapy in patients with inflammatory bowel disease, owing to its robust study design and high power. Given the compelling results of the PUCCINI trial, in addition to several negative studies examining vedolizumab and ustekinumab, we recommend that all biologic therapy be continued preemptively in both Crohn disease and ulcerative colitis patients.

However, biologic therapy does not need to be continued preemptively in all cases. For instance, in patients with stricturing Crohn disease undergoing intestinal resection with no plans for biologic therapy postoperatively, preoperative biologic therapy may not be warranted.

As demonstrated by the PUCCINI trial, there is no benefit in measuring serum anti-TNF levels preemptively. Further, drug levels of other biologic agents have yet to be studied, and thus in the absence of any supporting data, its practice should not be adopted.

The above recommendations pertain to intra-abdominal surgeries only, as only these surgeries were included in the referenced studies.

#### Small molecules

With respect to tofacitinib, in the absence of any data examining its perioperative use in inflammatory bowel disease patients, our recommendation reflects the 2017 ACR/AAHKS guidelines based on evidence from prior studies in patients with rheumatic diseases. These guidelines reflect the markedly short half-life of tofacitinib, which is 3.2 hours.18 Therefore, we recommend holding the medication 7 days before surgery and resuming as early as 14 days after surgery. It should be noted, however, that for urgent or emergent situations, we would not delay surgery due to any biologic or small molecule therapy. The increased risk of postoperative complications, if even present, does not outweigh the risks of delaying surgery.

Selective JAK inhibitors, namely filgotinib, upadacitinib, and peficitinib, have shown promising preliminary results in clinical trials and may soon be approved for treating inflammatory bowel disease. Because these drugs are so new, their influence on operative outcomes at this time is unknown.
