Crowned dens syndrome: Caution about asymptomatic calcification

Crowned dens syndrome is relatively benign, but infection of the central nervous system needs prompt intervention

Figure 1. Noncontrast computed tomography of the head and neck showed calcification around the dens (arrow).

AN 88-YEAR-OLD JAPANESE MAN in a psychiatric hospital because of progressive Alzheimer disease developed fever, headache, and posterior neck pain. The symptoms persisted despite antibiotic therapy with 500 mg/day of oral levofloxacin and 500 mg/day of intravenous meropenem. He was transported to our emergency department 42 days after the onset of symptoms.

muscular pain, arthralgia, rash, or abdominal pain. Laboratory tests revealed a white blood cell count of $3.43 \times 10^9/L$ (reference range 3.59–9.64) and a C-reactive protein level of 0.95 mg/dL (0–0.30).

Computed tomography of the head and neck without contrast enhancement showed calcium deposition around the dens (**Figure 1**). Cerebrospinal fluid obtained by lumbar puncture was colorless and transparent and showed no red blood cells or white blood cells.

Based on the persistence of headache and neck pain despite antibiotic therapy and on calcification around the dens, a tentative diagnosis of crowned dens syndrome was made. The patient was prescribed a nonsteroidal anti-inflammatory drug (loxoprofen 60 mg), to be used as needed.

Bacterial culture of the cerebrospinal fluid came back 2 days later positive for *Bacillus cereus*. Therefore, the patient was diagnosed with bacterial meningitis, partially treated with previously administered antibiotics. He was quickly admitted to our hospital and started on intravenous vancomycin 750 mg every 24 hours and clindamycin 600 mg every 8 hours. His fever, headache, and cervical pain diminished gradually, and he was discharged to home on day 57.

■ IS IT INFECTION OR CROWNED DENS?

Crowned dens syndrome is characterized by acute-onset fever, head and cervical pain, and radiographic findings of calcium deposition around the dens.¹ The calcification in our patient was thin, with no adjacent soft-tissue

swelling. Advances in computed tomography enable the detection of slight calcifications²; slight calcifications may be normal and should not raise unnecessary suspicion for crowned dens syndrome.

This patient's case conveys the important message that calcium deposition in the atlantoaxial joint is not always symptomatic. It remained unclear whether the patient developed crowned dens syndrome with infection or just the infection.

Although crowned dens syndrome is relatively benign, infection of the central nervous system is a critical condition that needs prompt intervention. Physicians should not rule out infectious disease based only on a finding of calcium deposition.

HEEDING THE CLUES

Asymptomatic atlantoaxial calcium deposition is reportedly common in the aged population.³ In the present case, the prolonged period of fever was inconsistent with crowned

dens syndrome, which usually develops acutely and subsides within a few days. In addition, inappropriate antibiotic use might lead to partial treatment of meningitis, pseudonegative cerebrospinal fluid findings, and, in this case, delayed diagnosis.

In summary, physicians should be aware that the combination of fever, headache, cervical pain, and calcium deposition around the dens does not always indicate crowned dens syndrome. Asymptomatic calcification is not rare, and physicians should not hesitate to perform lumbar puncture and other diagnostic tests to rule out life-threatening diseases such as bacterial meningitis. ■
